Introduction

This reference guide provides information about the Simple Network Management Protocol (SNMP) Management Information Base (MIB) which is applicable for Dell OpenManage Version 7.1.

NOTE: This guide contains information that may also be applicable to earlier OpenManage supported platforms.

This introduction is divided into two sections. The first section. "Introduction to the SNMP Reference Guide" on page 18, explains the SNMP Reference Guide design. All essential Simple Network Management Protocol (SNMP) terms are defined in this section. Some of the vocabulary may seem complex and unfamiliar to system administrators who are using SNMP for the first time. SNMP experts can skim this section, and beginners can read the section more carefully.

The second section, "Introduction to the Server Administrator SNMP Subagent" on page 33, is a more technical introduction to the management information base (MIB) that underlies Server Administrator services.

Server Administrator Instrumentation MIB

The Server Administrator Instrumentation MIB (filename 10892.mib) provides instrumentation data that allows you to monitor the health of a system with SNMP management applications. It provides:

- Information about the status of temperatures, power supplies, voltages, currents, fans, and memory at key points in the system
- Rapid access to detailed fault and performance information gathered by industry standard systems management agents
- Version information for Basic Input/Output System (BIOS), firmware, and operating system

SNMP Basic Terminology

It is important to have a good understanding of the key technical terms used in this guide. This guide provides definitions for all essential terms used in describing the Server Administrator MIBs. For definitions on all essential terms and acronyms, see the *Glossary* available on the Dell Support website at support.dell.com/manuals.

SNMP Master Agent

Typically, the SNMP agent on a managed system consists of one SNMP master agent and zero or more SNMP extension agents. This SNMP agent extendable structure facilitates the addition of new MIB modules without having to rebuild the entire SNMP agent and is invisible to SNMP management applications.

The SNMP master agent is responsible for receiving SNMP request protocol messages from SNMP management applications and sending SNMP response protocol messages. As part of processing SNMP request protocol messages, the SNMP master agent typically communicates with one or more SNMP extension agents. This communication does not involve standard SNMP protocol messages. The SNMP master agent uses an extension protocol that shields the SNMP extension agent from the standard SNMP protocol messages. The extension protocol also provides a way for SNMP extension agents to send SNMP event notifications (called traps in SNMPv1). The SNMP master agent is also responsible for sending SNMP event notification protocol messages to SNMP management applications.

On supported operating systems, the SNMP master agent is provided with the operating system. For example, on supported Microsoft Windows operating systems, the Windows SNMP service is the SNMP master agent. For information on the versions of the SNMP protocol supported by the SNMP master agent, see the operating system documentation.

SNMP Extension Agent

The SNMP extension agent is responsible for registering the MIB objects that it supports with the SNMP master agent and then processing requests from the SNMP master agent for those MIB objects. The SNMP extension agent also initiates event notifications to the SNMP master agent. The SNMP extension agent does not receive or send standard SNMP protocol messages. The SNMP extension agent communicates with the SNMP master agent using an extension protocol defined by the SNMP master agent. The Server Administrator SNMP subagent is an SNMP extension agent.

Managed Object

A managed object is any item in a computer system that can be singled out for discovery, monitoring, or user intervention and correction.

NOTE: Not all managed objects described in this guide are supported by all systems.

MIB

A MIB acts as a structured road map for managed objects. As an Application Programming Interface (API), a MIB allows systems management tools to retrieve data maintained by an agent. The server administrator MIB is divided into several major groups of managed objects.

Variable

A variable is a component of a managed object. A temperature probe, for example, has a variable to describe its capabilities, its health or status, and certain indexes that you can use to locate specific temperature probes. One index for the probe would be the probe's chassis number. Some systems may have multiple chassis—one chassis for the central processing unit and another chassis for storage. A chassis within a system can also have more than one temperature probe. Variables for a temperature probe include its capabilities, status, chassis index, and index.

One-Based Index

When an index is one-based, counting starts at 1. One-based indexing counts the first instance as 1, the second index as 2, and so on.

Zero-Based Index

When an index is zero-based, counting starts at 0. Zero-based indexing counts the first instance as 0, the second index as 1, and so on.

Fields

Managed object variables contain fields. In this reference guide, managed object variables have the following fields defined:

Name is the exact string by which the variable is known in the MIB. MIB variables are named according to the following conventions:

- Variable names start with a lowercase letter.
- Spaces are not allowed between words in the variable name.
- Acronyms are in uppercase letters, except when an acronym is the first word in the variable name.
- With the exception of the first letter of the variable name and acronyms, all other words in the variable name start with capital letters.

The following variable names illustrate these conventions:

- temperatureProbeLowerCriticalThreshold
- coolingUnitIndex
- pCIDeviceSpeed

Object Identifier (OID) is the unique number assigned to an object defined in a MIB. An OID is written as a sequence of subidentifiers in decimal notation. Each OID in this reference guide has a prefix that identifies the managed objects as belonging to Dell: 1.3.6.1.4.1.674. The additional numbers identify the MIB group and subgroup as well as the table entry number of any variables.

For example, the OID for the temperature probe managed object table is 700.20 and the variable for the location of the temperature probe (temperatureProbeLocationName) has an OID of 700.20.1.8. The full OIDs for these items are 1.3.6.1.4.1.674.10892.1.700.20 for the temperatureProbeTable and 1.3.6.1.4.1.674.10892.1.700.20.1.8 for the temperatureProbeLocation. For more information about the structure of OIDs, see "SNMP Management Information Base Object Identifiers" on page 35.

Description is a brief explanation of what a particular managed object does.

Syntax defines the data type in which the values of the variable must be expressed. Most variables in this reference guide use standard data types such as string or boolean. All data types that are unique to server administrator variables are defined at the end of the section in which they occur. Standard data types are defined in "Standard Data Type Definitions" on page 801.

Access specifies whether persons with administrative privileges can read but not modify the value of a variable (read only) or can both read and modify the value of a variable (read-write).

Frequently Used Terms in Variable Names

The following terms are frequently used in the name of a MIB variable:

Capability refers to the actions an object can perform, or to actions that can be taken by the object. Hot-pluggable is an example of a capability. If a card is hot-pluggable, it can be replaced while a system is running. Capability settings refer to the capabilities of the object that the user can select from and activate if desired. Capability settings allow users of the server administrator to predetermine how an object behaves under specific conditions.

Settings are the conditions of a manageable object that determine what happens when a certain value is detected in a component. For example, a user can set the upper critical threshold of a temperature probe to 75 degrees Celsius. If the probe reaches that temperature, the setting causes an alert to be sent to the management console. Some settings, when reached, can trigger a system shutdown or other response to prevent damage to the system.

State refers to the condition of an object that has more than one condition. For example, an object may be in a *not ready* or in an *enabled* state.

Status refers to the health of an object or how the object is functioning. For example, the status of a temperature probe that is measuring acceptable temperatures would be reported as normal. When the probe begins reading temperatures that exceed limits set by the user, it reports a critical status.

Tables

This reference guide contains two types of tables: tables that are used to organize and define variable values and tables that define MIB objects. Readers must understand the difference between these two types of tables.

SNMP Tables

Most of the MIB objects defined in this reference guide are organized into SNMP tables. SNMP tables organize data into two-dimensional structural arrays. In SNMP, objects that have a relationship to other objects are called columnar objects. Columnar objects are objects used to form lists and tables. When a MIB group is divided into one or more discrete tables, the word *table* has a technical meaning. An example is the section of this reference guide entitled Universal Unique Identifier (UUID). The UUID object has a type and a value that uniquely identifies an object such as a chassis. The table defines all of the variables that comprise the managed object UUID.

The following table is an example of an SNMP table. The table contains variables that must occur in a definite sequence. In the example table the defined variables are UUID Chassis Index, UUID Index, UUID Type, and UUID Value.

Reference Guide Content Tables

NOTE: Variable values are defined for any variable that is Server Administrator-specific. Industry-standard variable definitions are documented in "Standard Data Type Definitions" on page 801.

Some of the tables in this guide have no technical significance in SNMP. These tables are designed to show information in a readable form. The following table, for example, defines the Server Administrator-specific variable, DellFanControlCapabilities. The table provides the name of the variable, its data type, the values that are valid for the variable, and the meaning of each value.

Table 1-9. Example Variable Type Definition Table

Variable Name: DellFanControlCapabilities

Data Type: Integer

Possible Data Values	Meaning of Data Value
unknown(1)	The fan's capabilities are unknown.
lowSpeedCapable(2)	The fan can be set to low speed.
highSpeedCapable(4)	The fan can be set to high speed.
lowOrhighSpeedCapable(6)	The fan can be set to low or high speed.

This type of table is used throughout the reference guide to list and define variable values. Tables that explain Server Administrator-specific variable values are located in the final section of sections that define Server Administrator-specific variables. In the preceding example, the variable name is DellFanControlCapabilities. This variable must be expressed as an integer and has four possible values: unknown, lowSpeedCapable, highSpeedCapable, and lowOrhighSpeedCapable.

Section Organization

Sections in this reference guide are based on the Server Administrator MIBs, so the complexity of each section depends on the complexity of each MIB group. The first section provides a high-level introduction to the MIB group. If the group is defined by one or more tables, the second section lists these tables. The third section documents the variables that comprise the group, and if applicable, the variables that comprise the tables. The fourth section contains definitions for any Server Administrator-specific variables that are used in the section. The following example shows the typical content of these four sections:

1 BIOS Setup Control Group

This section explains the purpose of the MIB group and summarizes the major features of the component groups.

2 BIOS Group Tables

If there is more than one SNMP table for a group, this section lists all of the tables. For this BIOS group example, there are eight tables listed. In each section, double-clicking any table on the list takes you to that table.

- BIOS Setup Control Table
- SCSI Control Table
- Parallel Port Control Table
- Serial Port Control Table
- USB Control Table
- IDE Control Table
- Diskette Control Table
- Network Interface Control Table
- **3** Variables that make up each table in the group

This section documents the variables for the eight tables that comprise the BIOS group.

4 BIOS Variable Values

This section explains any Server Administrator-specific variables and data types that are used in this section. In the BIOS group example, there are 17 unique, Server Administrator-specific variable meanings. Information on each Server Administrator-specific variable is presented in a formatted table.

Other Documents You May Need

In addition to this guide, you can access the following guides available on the Dell Support website at support.dell.com/manuals. On the Manuals page, click Software→ Systems Management. Click the appropriate product link on the right-side to access the documents.

- The Server Administrator Messages Reference Guide lists the messages that
 you can receive on your systems management console or on your operating
 system's event viewer. This guide explains the text, severity, and cause of
 each message that the server administrator issues.
- The Server Administrator CIM Reference Guide documents the Common Information Model (CIM) provider, an extension of the standard management object format (MOF) file. The Server-Administrator CIM provider documents supported classes of management objects.
- The *Glossary* provides information on the terms used in this document.

Introduction to the Server Administrator SNMP Subagent

This guide provides formatted information drawn primarily from the MIB files written for the Server Administrator services that support the SNMP protocol.

For each of the variables defined in the MIBs, the following fields are specified:

- Variable name
- OID or unique identifying number
- Description
- Data type of the variable (for example: integer, string, octet string)
- Whether the variable is accessible, not accessible, read-only, or read-write
- Index or indexes, if applicable

For each MIB group that has unique variable definitions, tables are included in the last section of the section to explain the meaning of the terms.

Standards for writing MIBs are defined by the Internet Engineering Task Force (IETF). Structure of Management Information (SMI) is a standard that specifies the rules for defining the structure and type of managed objects and events in a MIB. SMIv1 is specified in Request For Comments (RFC) 1155. The Server Administrator MIB conforms to the SMIv1 standard.

SNMP is a systems management standard originally designed for network management. SNMP manages much more than networks. Information Technology (IT) professionals use SNMP for monitoring and managing computer systems and the various components and peripherals supported by their systems.

SNMP standards are defined by the Internet Engineering Task Force (IETF). SNMP version 1 was published in August 1988 and is the most commonly supported version of SNMP SNMP version 2 was first published in May 1993, but has not gained widespread market acceptance. SNMP version 3 was recently completed and has addressed security issues that exist in version 1.

All SNMP systems consist of one or more managed systems that provide data through an SNMP agent to a management system. The management system provides a user interface to view data from the managed systems. The management system and managed systems communicate over a network (typically through User Datagram Protocol/Internet Protocol [UDP/IP]).

The management system and a managed system communicate by means of a common data schema. SNMP MIB files define the structure, type, and values of the SNMP data. While MIBs can be standardized or enterprise specific, most operating systems supply SNMP agents for the standard MIB-I and MIB-II schemas. MIB-I defines a base set of standard management information for systems implementing the Internet Protocol (IP) suite. MIB-II defines characteristics of the system, characteristics of network interfaces, and characteristics of components of the IP on the system. In addition to the standard MIBs, many hardware vendors have defined MIBs that provide management data specific to their systems and peripheral devices.

Monitored data can be retrieved through SNMP using the Get command. Typically, this command requires the host name or IP address of the target machine as well as the OID of the data to retrieve. Exact details are dependent on the operating system and the development tools being used to create the management application. The Get command has a variant known as GetNext.

SNMP Management Information Base Object Identifiers

Each data class within a Management Information Base (MIB) is defined by an Object Identifier (OID). OIDs are unique across all MIBs. An OID consists of a series of digits separated by periods. The OID functions in a similar fashion to a phone number. The phone number 011-512-471-0000 uniquely identifies a single phone. The phone number can be broken down into a number of components to uniquely identify a phone. The first component, 011, is the country code for the United States. The second component, 512, identifies the area code for central Texas. The third component, 471, is the phone exchange for a large state university in the city of Austin. The final component, 0000, is the main switchboard.

There are two main differences between the phone number example and an actual OID. The first difference is that there are many more components in an OID, up to 128. The combination of these components is called an OID prefix. The second difference is that OIDs support the concept of indexes or keys. The OID prefix specifies the data class but does not specify an instance of the data within the class. Indexes can be used to identify the instances of a data class. These indexes are referred to as the OID suffix.

The assignment of values for each OID prefix component can be illustrated by using a tree structure. The following is an example of an OID assignment:

ROOT

```
CCITT(0)
ISO(1)
ORG(3)
DOD(6)
INTERNET(1)
MGMT(2)
MIB(1)
EXPERIMENTAL(3)
PRIVATE(4)
ENTERPRISES(1)
DELL
(674)
SNMPv2(6)
```

In the preceding example, the OID prefix for the Dell enterprise would be 1.3.6.1.4.1.674.

The numbers in boldface type show the categories and numbers that apply to Server Administrator, All Server Administrator-defined OIDs consist of 1.3.6.1.4.1.674 followed by additional component values.

SNMP Security

SNMP version 1 has a very limited security mechanism. SNMP agents support the use of a community string, which is configured at each SNMP agent and is passed as a part of all SNMP request messages. There is no verification that the requester is actually a member of the specified community. As most system and network management data is not confidential, this limited security is acceptable for Get types of requests. On the other hand, this security is not acceptable for Set types of operations where an SNMP request could power off a system, reconfigure a redundant array of independent disks (RAID) card, and so on. Some vendors have chosen not to support SNMP Set operations for this reason. Server Administrator is able to support SNMP Set operations because its SNMP agents implement a hash/digest mechanism to prevent unauthorized SNMP Set operations. One limitation of this practice is that only server administrator-developed SNMP management applications have the capability to support the hash/digest mechanism.

NOTE: The default SNMP agent configuration usually includes a SNMP community name such as public. For security reasons, change the SNMP community names from their default values. For information about changing SNMP community names. see the Dell OpenManage Server Administrator User's Guide available on the Dell Support website at support.dell.com/manuals. For additional guidelines, see the Securing an SNMP Environment article, dated May 2003, in the Dell Power Solutions magazine. This magazine is also available at **dell.com/powersolutions**.

NOTE: Server Administrator provides support to enable or disable SNMP Set operations. For more information on enabling or disabling SNMP Set operations in Server Administrator, see the Dell OpenManage Server Administrator User's Guide or the Dell OpenManage Server Administrator Command Line Interface User's Guide on the Dell Support website at support.dell.com/manuals.

Management Actions

Management actions can be performed using the SNMP Set command. These actions can consist of configuring a phone number for the system's owner, rebooting a system, or changing the asset tag of the system. See the previous section, "SNMP Security" on page 36, for limitations on Set operations.

SNMP Traps

SNMP is frequently used to monitor systems for fault conditions such as temperature violations, hard drive failures, and so on. Management applications can monitor for these conditions by polling the appropriate OIDs with the Get command and analyzing the returned data. This method has its drawbacks. If it is done frequently, significant amounts of network bandwidth can be consumed. If it is done infrequently, the response to the fault condition may not occur in a timely fashion. SNMP traps avoid these limitations of the polling method.

An SNMP trap is an asynchronous event indicating that something significant has occurred. This is analogous to a pager receiving an important message, except that the SNMP trap frequently contains all the information needed to diagnose a fault.

Two drawbacks to SNMP traps are that they are sent using UDP, which is not a guaranteed delivery mechanism, and that they are not acknowledged by the receiver.

An SNMP trap message contains the trap's enterprise OID, the agent IP address, a generic trap ID, the specific trap ID, a time stamp, and zero or more variable bindings (varbinds). The combination of an enterprise OID and a specific trap ID uniquely identifies each Server Administrator-defined trap. A varbind consists of an OID and its value and provides additional information about the trap.

In order for a management system to receive SNMP traps from a managed system, the node must be configured to send traps to the management system. Trap destination configuration is dependent on the operating system. When this configuration is done, a management application on the management system can wait for traps and act on them when received.

Systems Management Software Group

The Systems Management Software Group allows users to see information about the standards and software that are supported by the agent of a particular managed computer chassis. The Systems Management Software Group classifies each computer chassis according to the systems management standard that the agent supports.

Additional objects define the universal resource locator (URL) of the systems management software and the language in which systems management information displays. Defining these objects enables users to manage a system using an internet browser. You can access Server Administrator using the secure hypertext transfer protocol (https) and a pre-assigned port number of 1311, or you can specify a port number of your own choosing.

NOTE: Using the Software → Server Preferences menu of Server Administrator, you can bind to either one IP address or to all IP addresses.

To manage a system locally using Server Administrator, type the following in the address field of your browser: https://localhost:<1311 or user-specified port number>

To manage a system remotely using Server Administrator, type one of the following in the address field of your browser:

https://<systemname>:<1311 or user specified port number> or https://<IP address>:<1311 or user specified port number>

System State Group

The Management Information Base (MIB) variables presented in this section enable you to track various attributes that describe the state of the critical components supported by your system. Components monitored under the System State Group include power supplies, AC power cords, AC power switches, and cooling devices, as well as temperature, fan, amperage, and voltage probes.

System State Group Table

The System State Group defines objects in the System State MIB table.

System State Table

The systemStateGlobalSystemStatus variable provides overall system health status and includes rolled-up (that is, worst) status for Instrumentation and Storage. This variable monitors the overall system health status. It reflects changes to systemStateChassisStatus variable, which represents Instrumentation health status and agentGlobalSystemStatus (dcstorag.mib), which represents Storage health status.

The systemStateChassisStatus variable provides the rolled-up health status for the subsystems associated with the chassis that is represented by the row in the systemStateTable. Changes to the variables in "List 1" on page 50, each of which indicates the rolled-up health status of all the components of the corresponding subsystem, are reflected in systemStateChassisStatus variable.

For example, systemStatePowerSupplyStatusCombined provides the rolledup status of all power supplies for the chassis.

The variables in "List 2" on page 50 provide the health status of each component of the corresponding subsystem. Each octet of the value represents a component. If a power supply fails, the corresponding entry in systemStatePowerSupplyStatusDetails,

systemStatePowerSupplyStatusCombined, systemStateChassisStatus, and systemStateGlobalSystemStatus transitions to critical.

Power Group

The Power Group provides information about power units (a group of power supplies in a system chassis), power supplies, and voltage and amperage probes.

NOTE: Power Management features are only available for PowerEdge systems that have hot-swappable power supplies and not systems that have a fixed, nonredundant power supply installed.

Power Group Tables

The following management information base (MIB) tables define objects for the Power Group:

Memory Group

The Memory Group provides information about the physical memory in your system. Variables in this group include error correction type, location, and different types of memory use, such as cache, flash, system, video, and nonvolatile memory.

Physical Memory Tables

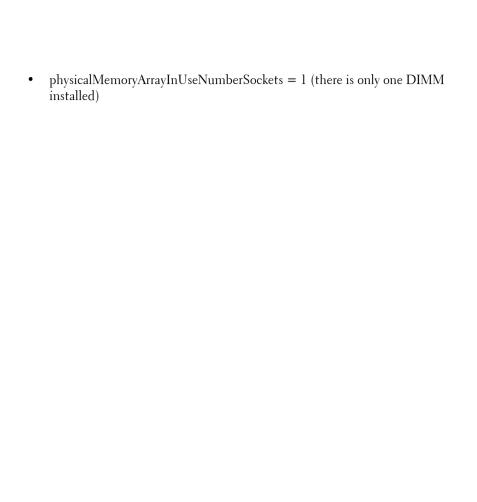

The following management information base (MIB) tables define the objects in the Memory Group:

- "Physical Memory Array Table" on page 365
- "Physical Memory Array Mapped Table" on page 371
- "Physical Memory Configuration Table" on page 374
- "Physical Memory Logging Table" on page 377
- "Redundant Memory Unit Table" on page 379
- "Physical Memory Card Table" on page 382

Physical Memory Array Table

The physical memory array is the entire physical memory of a system. The example that follows shows variable values for a system that has one 128-megabyte (MB) dual in-line memory module (DIMM):

- physicalMemoryArrayMaximumSize = 2,097,152 kilobytes (KB) or 2 gigabytes (GB)
- physicalMemoryArrayTotalNumberSockets = 4 (the example system has four DIMM slots on the motherboard)

BIOS Setup Control Group

Basic Input/Output System (BIOS) Setup Control Group variables provide information about the functions that the BIOS performs in your system. This management information base (MIB) group includes variables for the boot sequence, speakers, diskettes, ports, network interface controllers (NICs), and the Wakeup on local area network (LAN) feature.

BIOS Setup Control Group Tables

The MIB tables in this group define the BIOS control of devices and controller cards that are typically present in a system.

- "BIOS Setup Control Table" on page 391
- "SCSI Control Table" on page 402
- "Parallel Port Control Table" on page 404
- "Serial Port Control Table" on page 406
- "USB Control Table" on page 408
- "IDE Control Table" on page 410

Local Response Agent Group

The Local Response Agent Group provides information about various attributes of your system's local response agent (LRA). The LRA allows systems managers to predetermine how a system running the server administrator responds to a particular event type, such as the loss of redundancy in a specific component or the elevation of temperature in a chassis. Systems managers can configure the LRA to respond to an event type with a specific action. When the condition of the critical component worsens, the systems manager can escalate the response to make it more obvious to the operator.

For example, when a voltage probe on a monitored machine reaches a warning condition, the systems manager may want to notify the operator by causing the machine to beep. When the voltage probe reaches failure, the systems manager might want to have the system that has a failing component send a broadcast message to the management system and power off the troubled system.

LRA Group Tables

The following management information base (MIB) tables define LRA variable attributes:

- "LRA Global Settings Table" on page 432
- "LRA Action Table" on page 434

LRA Global Settings

The global settings table allows the systems manager to determine what LRA capabilities exist for a specific system that is running Server Administrator. Some machines may support all or some of the capabilities described in DellLocalResponseAgentCapabilitiesUnique. The LRA Global Settings Table also defines thermal shutdown capabilities and settings. In the event that a temperature probe determines the temperature is at or over the failure limit, the systems manager can set an action to be taken automatically.

Cluster Group

Clustering combines multiple systems in such a way that they provide services a single system cannot. Clustering enhances higher availability, scalability, and management. Higher availability is achieved by using *failover* clusters, in which resources can automatically move between two or more systems in the event of a failure. Scalability is achieved by balancing the load of an application across several computer systems. Simpler management is achieved by using virtual servers, as opposed to managing each individual computer system.

Cluster Group

The Cluster Group defines attributes such as the number of systems in the cluster, capabilities of the cluster, type of cluster, and name of the cluster.

The following table defines the attributes of the cluster.

Baseboard Management Controller Group

The Baseboard Management Controller (BMC) monitors the system for critical events by communicating with various sensors on the system board and sends alerts and log events when certain parameters exceed their preset thresholds. The BMC Group provides information about the BMC that may be present in your system. In addition to providing general information about the BMC, this group provides information about the serial and local area network (LAN) interfaces of the BMC.

Baseboard Management Controller Group Tables

The objects in the BMC group define information about the BMC and the serial and LAN interfaces that can be used to access the BMC remotely to perform management activities. Objects for the serial interface define the serial connection mode, flow control type and bit rate. Objects for the LAN interface define the media access control (MAC) address, internet protocol (IP) address, subnet mask and default gateway.

The following MIB tables define the BMC group:

- Baseboard Management Controller Table
- Baseboard Management Controller Serial Interface Table
- Baseboard Management Controller LAN Interface Table

Logical Devices Group

The Logical Devices Management Information Base (MIB) group provides information about the logical devices managed by the Dell Storage Management Software and their relationships to each other.

This group and all of its associated tables and objects are not supported on Microsoft Windows Advanced Server Limited Edition 64-bit operating system (Windows.Net-64) on a Dell PowerEdge 7150. The following MIB tables define objects and relationships, or connections among the objects, in the Logical Devices Group:

- Virtual Disk Table—describes available properties for each virtual disk on the managed system.
- Array Disk Logical Connection Table—describes the connections
 between array disks, the virtual disk to which they belong, and their
 associated logical disk. For each object in the table, its object number
 corresponds to an instance number in the appropriate MIB table for that
 object where all of the object properties can be found.

Traps

The Server Administrator generates events that result in Simple Network Management Protocol (SNMP) traps or operating system event logs. Remote Access Controller (RAC) and Baseboard Management Controller (BMC) can also generate SNMP traps in response to hardware events. This section describes the traps, also known as alerts, generated by the Server Administrator, RAC, and BMC.

The Server Administrator generates events in response to changes in the status of sensors and other monitored parameters. When an event with predefined characteristics occurs on your system, the SNMP subagent sends information about the event, along with trap variables, to the management console.

Each status change event generates a unique identifier called the TrapID and a trap description that describes the event. The TrapID and message uniquely describe the severity and cause of the event, and provide other relevant information such as the location of the event and the monitored item's previous state.

"Instrumentation Traps" on page 696 lists all Server Administrator Instrumentation TrapIDs in numerical order and includes each TrapID's corresponding description, severity level, and cause. Description text in brackets (for example, <State>) describes the event-specific information provided by Server Administrator.

"RAC Traps" on page 721 lists RAC TrapIDs in numerical order and includes each TrapID's corresponding description, severity level, and cause.

"BMC Traps" on page 726 lists BMC TrapIDs and includes each TrapID's corresponding description and severity level.

Trap Variables

This section describes the variables that are sent to the management console to provide additional information about a trap or alert generated by some event on your system. The trap variables presented here apply to all Instrumentation and RAC traps. Trap variables are sent in the order listed and

are reserved for use only in traps. When a varbind is created for a trap variable, a zero is appended to the object ID (OID) to create the OID for the varbind.

Understanding Trap Severity

Traps often contain information about values recorded by probes or sensors. Probes and sensors monitor critical components for values such as amperage, voltage, and temperature. When an event occurs on your system, the Server Administrator sends information about one of the following event types to the system management console:

Information/Informational—An event that describes the successful
operation of a unit, such as a power supply turning on or a sensor reading
returning to normal.

- Warning An event that is not necessarily significant, but may indicate a possible future problem, such as crossing a warning threshold.
- Critical/Error A significant event that indicates actual or imminent loss
 of data or loss of function, such as crossing a failure threshold or a
 hardware failure.

Instrumentation Traps

This section describes the traps that are generated by the Instrumentation service of the Server Administrator. All of the traps documented in this section belong to the MIB enterprise identified by OID 1.3.6.1.4.1.674.10892.1 and are sent with all of the trap variables documented in the section, "Trap Variables" on page 690. The trap variables are sent in the order in which they are listed. The messages in the **Description** fields below show the format of the message that is sent in the alertMessage varbind. If a message in a **Description** field has multiple lines, the message contains newline (0Ah) characters that are part of the value in the alertMessage varbind.

Chassis Intrusion Traps

Chassis intrusion traps are a security measure. Chassis intrusion means that someone is opening the cover to a system's chassis. Alerts are sent to prevent unauthorized removal of parts from a chassis.

Redundancy Unit Traps

Redundancy means that a system chassis has more than one of certain critical components. Fans and power supplies, for example, are so important for preventing damage or disruption of a computer system that a chassis may have extra fans or power supplies installed. Redundancy allows a second or *nth* fan to keep the chassis components at a safe temperature when the primary fan has failed. Redundancy is normal when the intended number of critical components are operating. Redundancy is degraded when a component fails but others are still operating. Redundancy is lost when the number of components functioning falls below the redundancy threshold.

The number of devices required for full redundancy is provided as part of the trap message when applicable for the redundancy unit and the platform. For more details on redundancy computation, please refer to the respective platform documentation.

Memory Device Traps

Memory device messages provide status and warning information for memory modules present in a particular system. Memory devices determine health status by counting the number of ECC memory corrections.

NOTE: A value of failure or non-recoverable does not indicate a system failure or loss of data, but rather that the specified system exceeded the specified ECC correction threshold. Although the system continues to function, you should perform system maintenance as described in Table 27-10.

Replace the memory module identified in the message during the system's next scheduled maintenance. The memory device status and location are provided.

Hardware Log Traps

Hardware logs provide hardware status messages to systems management software. On certain systems, the hardware log is implemented as a circular queue. When the log becomes full, the oldest status messages are overwritten when new status messages are logged. On some systems, the log is not circular. When the log becomes full, subsequent hardware status messages are lost. Hardware log sensor messages provide status and warning information about the noncircular logs that may fill up, resulting in lost status messages.

Storage Management Alert Reference

Storage Management's alert or event management features let you monitor the health of storage resources such as controllers, connectors, array disks, and virtual disks.

Alert Monitoring and Logging

The Storage Management Service performs alert monitoring and logging. By default, the Storage Management Service starts when the managed system starts up. If you stop the Disk Management Service, then alert monitoring and logging stops. Alert monitoring does the following:

- Updates the status of the storage object that generated the alert.
- Propagates the storage object's status to all the related higher objects in the storage hierarchy. For example, the status of a lower-level object are propagated up to the status displayed on the Health tab for the top-level storage object.
- Logs an alert into the Alert log and Microsoft Windows application log.
- Sends an Simple Network Management Protocol (SNMP) trap if the operating system's SNMP service is installed and enabled.

Viewing Alerts

Storage Management generates alerts that are added to the Windows application alert log and to the Server Administrator Alert log. To view these alerts in Server Administrator:

- 1 Select the **System** object in the tree view.
- 2 Select the Logs tab.
- **3** Select the **Alert** subtab.

You can also view these alerts in the Windows Event Viewer. Every alert consists of the following:

- Severity Shows the severity of alert.
- Date and Time Date and time when Storage Management logged the alert.
- **Description** A brief description of the alert. To expand or collapse the alert description, click the **Description** column heading.

Alert Severity Levels

Each alert message in the Storage Management alert log has a severity level which indicates the nature of the alert and is displayed in the Severity field of the alert message. The severity level indicates the nature of the alert.

The alert severity levels are as follows:

Table 28-1. Storage Management Alert Severity

Alert Severity	Component Status
OK/Normal/Informational	No action is required. The alert is provided for informational purposes and does not indicate an error condition. For example, the alert may indicate the normal start or stop of an operation.
Warning/Non-critical	A component requires attention. This alert indicates a potential problem, but does not necessarily mean that the system has currently lost data or is nonfunctional. For example, a Warning/Non-critical alert may indicate that a component (such as a temperature probe in an enclosure) has crossed a warning threshold.
Critical/Failure/Error	A component has either failed or failure is imminent. This alert indicates a serious problem such as data loss or a loss of function. For example, a Critical/Failure/Error alert may indicate that an array disk has failed.

SNMP Support for Storage Management Alerts

By default, Storage Management installs SNMP trap forwarding support. For this support to function, you should have SNMP installed on the managed system prior to installing Storage Management.

NOTE: For more information on installation requirements and SNMP, see the Server Administrator documentation.

SNMP Trap Forwarding

The Storage Management alerts are displayed in the Server Administrator alert log and are forwarded to the Windows application alert log. If you have SNMP installed on the managed system (and the SNMP service is running), the Storage Management alerts in the Windows application alert log are forwarded as SNMP traps. In order for these traps to be viewable, however, a target system or application must be configured to receive these traps. SNMP traps that are generated by Storage Management can be viewed in any standard SNMP-compatible enterprise management console.

The Windows SNMP service must be configured to forward the SNMP traps to the target system or application. When forwarding to an application, the application should also be configured to receive the SNMP traps. The IT Assistant application is already configured to receive the SNMP traps generated by Storage Management.

See your Windows operating system documentation for information on configuring the operating system to forward SNMP traps. This information may be located under such topics as "setting up SNMP" or "SNMP traps." When configuring SNMP for Windows, be sure that the SNMP traps are forwarded to the correct server. For information on configuring an application to receive SNMP traps, see the documentation for that application.

SNMP Trap Definitions

The Storage Management management information base (MIB) defines the SNMP traps that Storage Management generates. These traps correspond to the alerts documented in the "Alert Descriptions and Corrective Actions" on page 767 section. The MIB is located in ..\sm\mibs\dcstorag.mib, a subdirectory of the Storage Management installation directory.

NOTE: Storage Management supports trap forwarding on both 32-bit and 64-bit operating systems.

SNMP Trap Variables

The Storage Management SNMP traps use a set of variables that are included with every trap. These variables are the following:

- messageIDEvent
- descriptionEvent
- location Event
- objectNameEvent
- objectOIDEvent
- objectNexusEvent
- currentStatusEvent
- previousStatusEvent

Viewing SNMP Traps

SNMP traps that are generated by Storage Management can be viewed in any standard SNMP-compatible enterprise management console. These traps are defined in the Storage Management MIB. These traps correspond to the alerts documented in the "Alert Descriptions and Corrective Actions" section. For more information on the MIB and its structure, as well as a change history of the SNMP traps, see the "Introduction" on page 17 section. For more information on configuring SNMP, see "SNMP Support for Storage Management Alerts" on page 765.

Alert Descriptions and Corrective Actions

The alerts generated by the redundant array of independent disks (RAID) or Small Computer System Interface (SCSI) controllers and supported by Storage Management are displayed in the Server Administrator Alert subtab or through Windows Event Viewer. These alerts can also be forwarded as SNMP traps to other applications.

SNMP traps that are generated for the alerts are included in the Storage Management MIB. The SNMP traps for these alerts use all of the SNMP trap variables. For the list of storage management alerts and storage management messages, see the *Dell OpenManage Server Administrator Messages Reference Guide* available on the Dell Support website at support.dell.com/manuals.

iDRAC7 Traps

The iDRAC7 generates events that result in Simple Network Management Protocol (SNMP) traps and/or entries in the iDRAC7 Lifecycle Log. This section describes the traps, also known as alerts, generated by the iDRAC7.

The iDRAC7 generates events in response to changes in the status of sensors and other monitored parameters. When an event with predefined characteristics occurs on your system, the SNMP subagent sends information about the event, along with trap variables, to the management console.

Each event generates an identifier called the trap ID and a list of trap variables that provide additional details about the event. The trap variables are listed in the following "Trap Variables" on page 778.

The traps of the iDRAC7 MIB are organized into five subgroups of traps. Each subgroup corresponds to one of the five categories of events that iDRAC7 supports (the **System Health**, **Storage Health**, **Updates**, **Audit**, and **Configuration** categories). Here is a list of the trap subgroups are:

- System Trap Group
- Storage Trap Group
- Updates Trap Group
- Audit Trap Group
- Configuration Trap Group

The trap subgroups, and all the traps within each trap subgroup, are described and listed in sections following the "Trap Variables" section.

NOTE: The traps listed in this document can be correlated to specific events that are documented in the Dell Event Message Reference guide. There is 1-to-many relationship between SNMP traps and events in iDRAC7. To correlate a trap to a specific event or set of events, you can match the **Trap ID** value of a trap in this document to the **Trap/Event ID** value of events in the *Dell Event Message Reference* auide.

Trap Variables

This section lists the six variables that are sent with iDRAC7 traps to provide additional information about a trap or alert generated by some event on the system. The trap variables presented here apply to all iDRAC7 traps. The trap variables are sent in the order listed and are reserved for use only in traps.

Standard Data Type Definitions

This appendix contains definitions for data types that are standard in most contexts across the information technology industry. These are the most common data types for describing variable values defined in the 10892.mib, dcs3rmt.mib and dcs3fru.mib files. Server Administrator-specific variable values are defined in the last section of the section in which they are introduced

Common Data Types

Common data types include several types of strings, the object range, signed and unsigned bit ranges, and the familiar Boolean (true or false) data type.

Table 30-1. Common Data Types

Variable Name:	Definition
DellString	DisplayString (SIZE (064))
DellSecurityString	DisplayString (SIZE (0255))
DellCostofOwnershipString	DisplayString (SIZE (064))
DellObjectRange	INTEGER (1128)
DellUnsigned8BitRange	INTEGER (1256)
DellUnsigned16BitRange	INTEGER (165535)
DellUnsigned32BitRange	INTEGER (12147483647)
DellSigned32BitRange	INTEGER (-21474836472147483647)
DellBoolean	INTEGER (01 (FALSE = 0, TRUE = 1))

Variables with Data Types of State Capabilities and State Capabilities Unique

Variables with definitions of <variable name>StateCapabilities or <variable name>StateCapabilitiesUnique are integers representing a series of bit definitions. They are NOT enumerations and should be treated as bit fields. The value is passed as a decimal value. The decimal value should be converted to hex and the appropriate bits should be parsed from hex. Some of the more common bit combinations are defined in some variables, but not all combinations are or will be defined.

Table 30-2. Dell State Capabilities

Variable Name: DellStateCapabilities

Data Type: Integer

Possible Data Values	Meaning of Data Value
if set to zero(0)	The object has no capabilities.
unknownCapabilities(1)	The object's capabilities are unknown.
enableCapable(2)	The object can be disabled (offline, a binary 0 value) or enabled (online, a binary 1 value).
notReadyCapable(4)	The object is not ready.
<pre>enableAndNotReadyCapable (6)</pre>	Enable and not ready capable.

Table 30-3. Dell State Settings

Variable Name: DellStateSettings

Data Type: Integer

Possible Data Values	Meaning of Data Value
if set to zero(0)	The object has no settings capabilities and its state is disabled.
unknown(1)	The object's state is unknown.
enabled(2)	The object's state is disabled (offline, a binary 0 value) or enabled (online, a binary 1 value).
notReady(4)	The object is not ready.
enableAndNotReady(6)	The object is enabled and not ready.

Table 30-4. Dell Probe Capabilities

Variable Name: DellProbeCapabilities

Data Type: Integer

Possible Data Values	Meaning of Data Value
if set to zero(0)	The object has no capabilities.
upperNonCriticalThresholdSet Capable(1)	The upper noncritical threshold can be set.
lowerNonCriticalThresholdSet Capable(2)	The lower noncritical threshold can be set.
<pre>upperNonCriticalThresholdDef aultCapable(4)</pre>	The upper noncritical threshold can be set to default.
lowerNonCriticalThresholdDef aultCapable(8)	The lower noncritical threshold can be set to default.

Dell Status Data Types

Status data types include DellStatus, DellStatusRedundancy, and DellStatusProbe.

Table 30-5. Dell Status

Variable Name: DellStatus

Data Type: Integer

Possible Data Values	Meaning of Data Value
other(1)	The object's status is not one of the following:
unknown(2)	The object's status is unknown.
ok(3)	The object's status is OK.
nonCritical(4)	The object's status is warning, noncritical.
critical(5)	The object's status is critical (failure).
nonRecoverable(6)	The object's status is nonrecoverable (dead).

Table 30-6. Dell Status Redundancy

Variable Name: DellStatusRedundancy

Data Type: Integer

Possible Data Values	Meaning of Data Value
other(1)	The object's status is not one of the following:
unknown(2)	The object's redundancy status is unknown.
full(3)	The object is fully redundant.
degraded(4)	The object's redundancy has been degraded.
lost(5)	The object's redundancy has been lost.
notRedundant(6)	Redundancy does not apply or it is not redundant.

Table 30-7. Dell Status Probe

Variable Name: DellStatusProbe

Data Type: Integer

Possible Data Values	Meaning of Data Value
other(1)	The object's status is not one of the following:
unknown(2)	The status of the object is unknown.
ok(3)	The status of the object is OK.
nonCriticalUpper(4)	The object is at the noncritical upper limit.
CriticalUpper(5)	The object is at the critical upper limit.
nonRecoverableUpper(6)	The object is at the nonrecoverable upper limit.
nonCriticalLower(7)	The object is at the noncritical lower limit.
criticalLower(8)	The object is at the critical lower limit.
nonRecoverableLower(9)	The object is at the nonrecoverable lower limit.
failed(10)	The status of the object is failed.

Dell Date

Variable Name: DellDate

Data Type: DellUnsigned64BitRange Octet String (SIZE(8))

Full Dates

Variable Name: DellDateName

Data Type: DisplayString (SIZE (25))

Full dates are defined in the ASCII format:

yyyyMMddhhmmss.uuuuu+fff or yyyyMMddhhmmss.uuuuuu-fff

where yyyy is the year, MM is the month, dd is the day, hh are the hours, mm are the minutes, and ss are the seconds. uuuuuu is the number of microseconds, and +fff or

-fff is the offset from UTC in minutes. For example, Friday, October 31, 2001, at 6:05:19 PM CST would be represented as 20011031180519.000000-360.

The values are zero-padded, and if a valid value for a field is not deliverable, each character in the field is replaced with an asterisk (*) character.

SNMP Sample Output

This appendix contains the sample output from the Simple Network Management Protocol (SNMP) covering the first four groups of the Instrumentation management information base (MIB) sample output from the Simple Network Management Protocol (SNMP) covers the first four groups of the Instrumentation management information base (MIB). Values are shown for each object identifier (OID) in the Instrumentation MIB Version Group, the Systems Management Software Group, the System State Group, the Chassis Information Table, and Event Log Table. The data is from a Dell PowerEdge 2650 system.
